# A large portion of atmospheric reactive N is emitted by terrestrial activities

Gu et al. (2012)

## Health Damage Costs of Reactive N across China in 2008

In Europe, China, and the US, 80-90% of atmospheric  $\text{NH}_3$  is from agriculture

*Can we secure future food supply without sacrificing the clean air?*

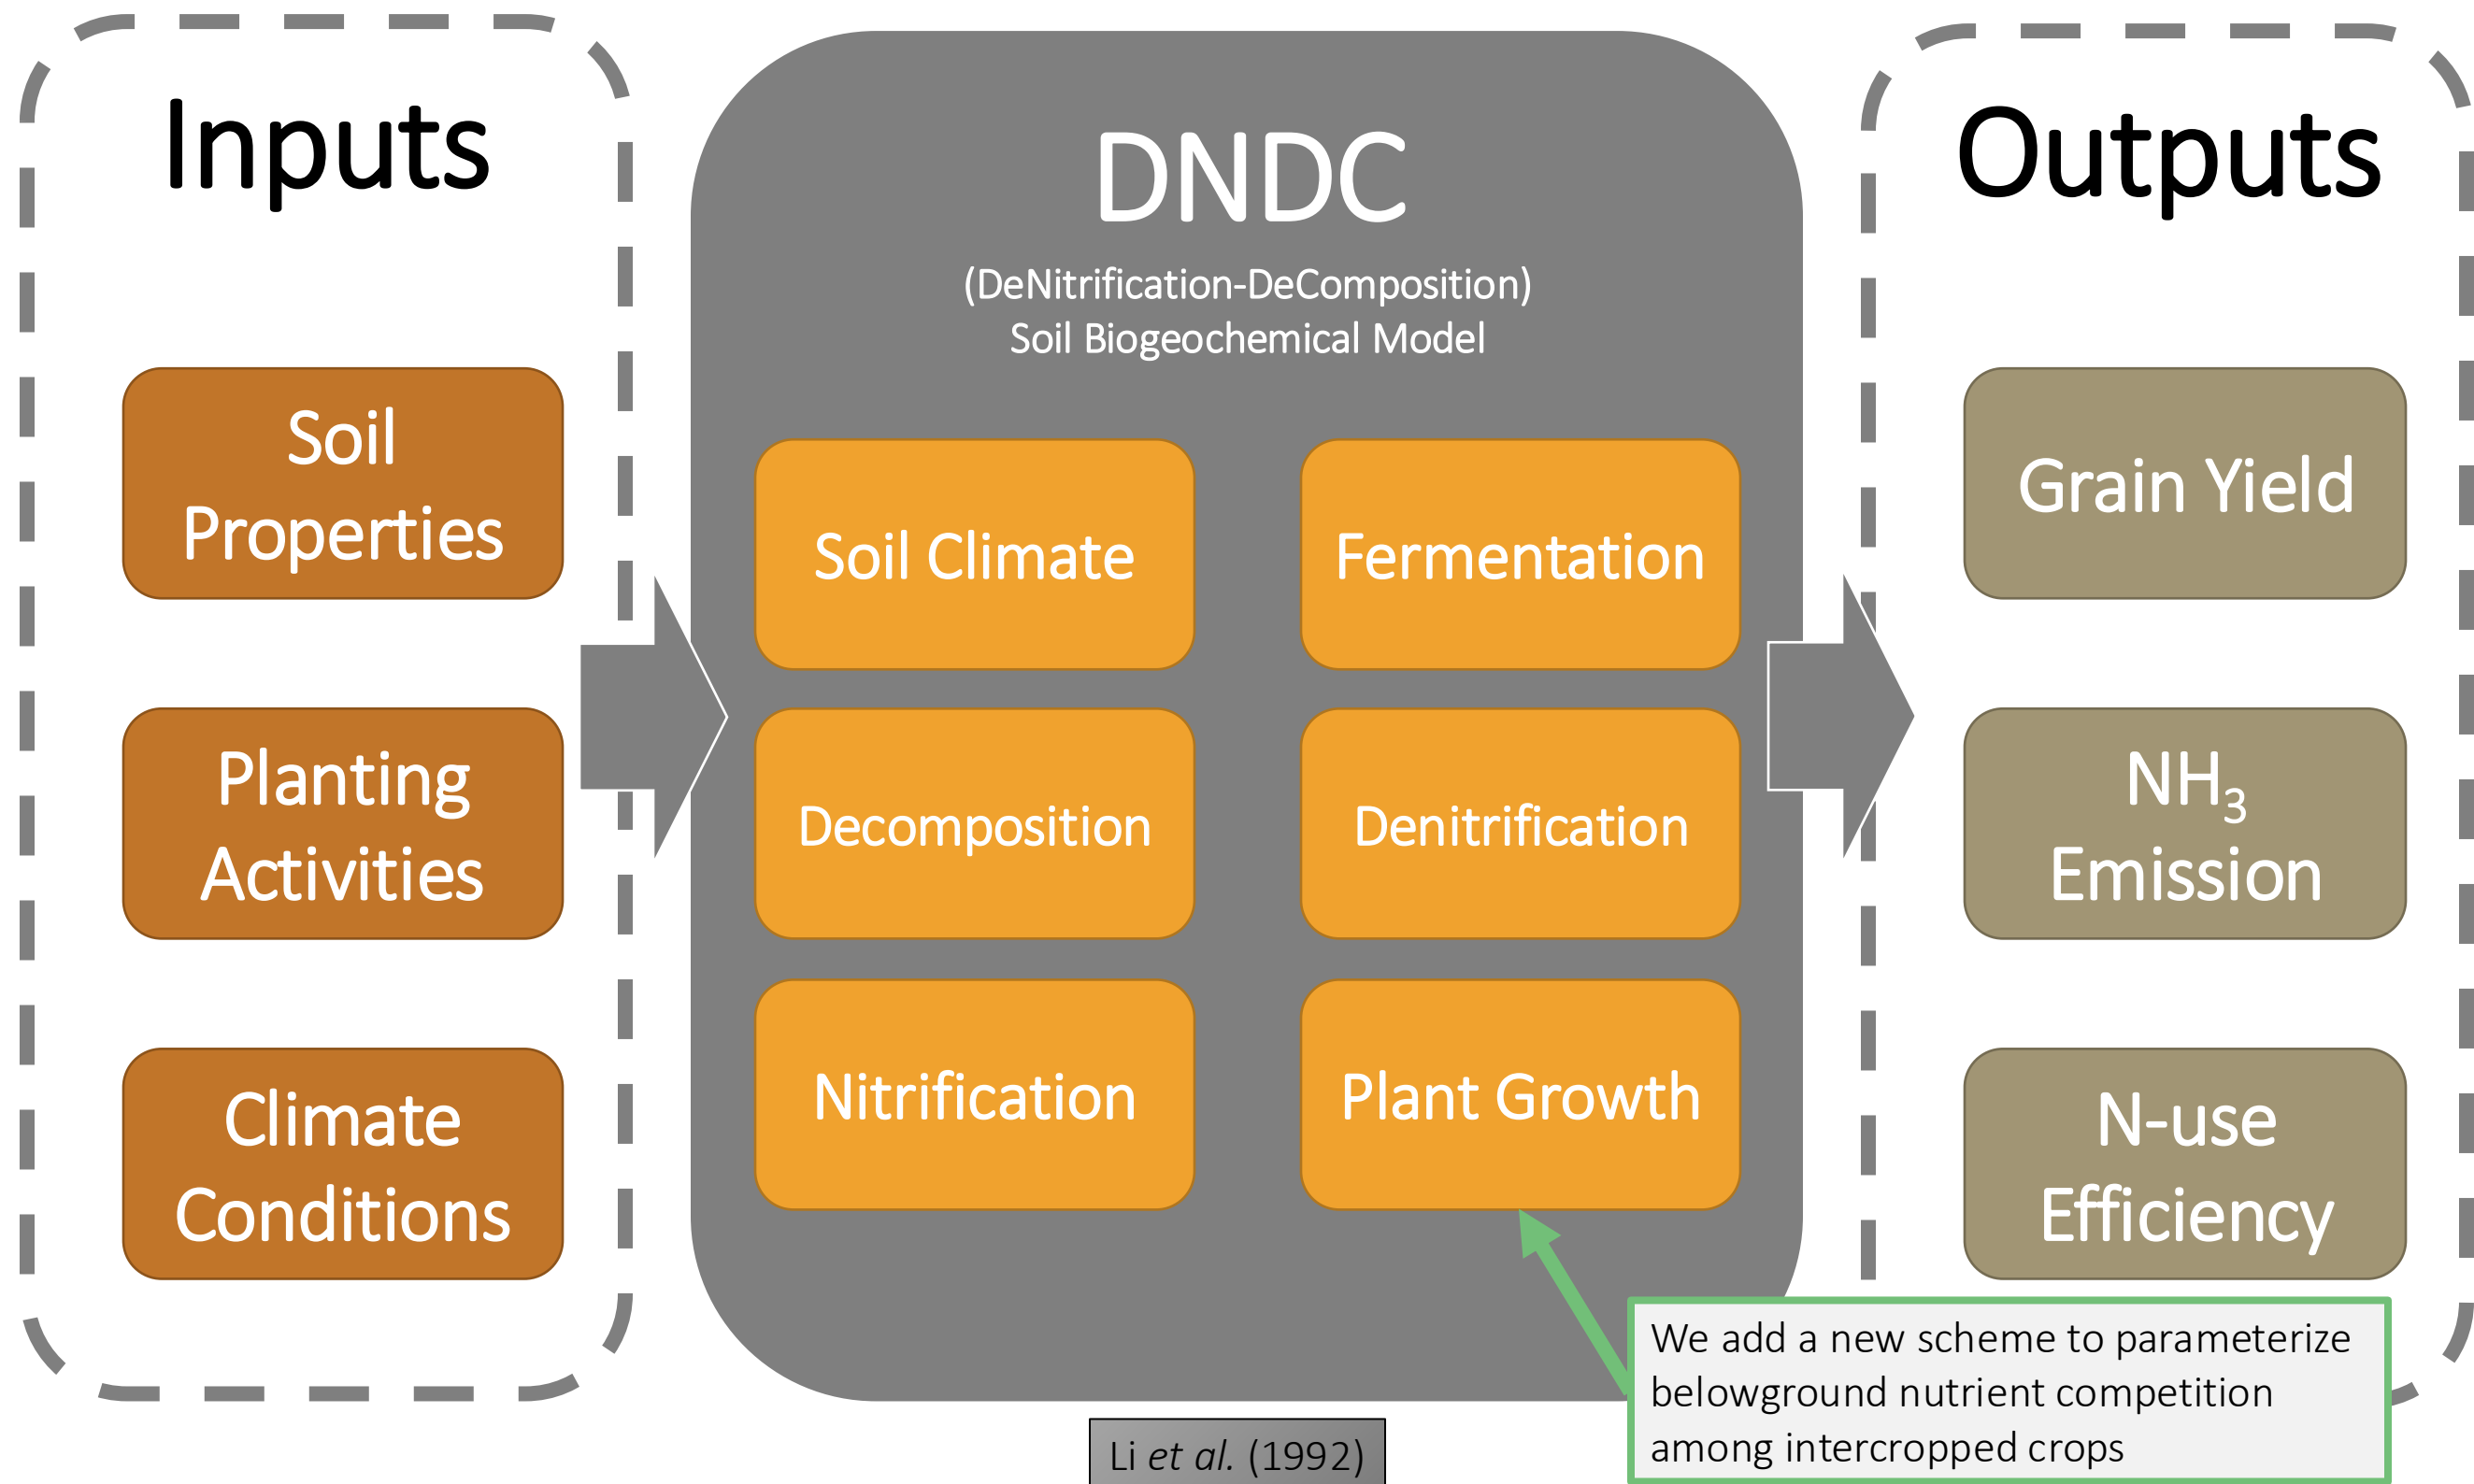

# Intercropping, a traditional wisdom, could be a way-out to this food-environment dilemma

Two or more crops are grown in alternate strips with a time-delay

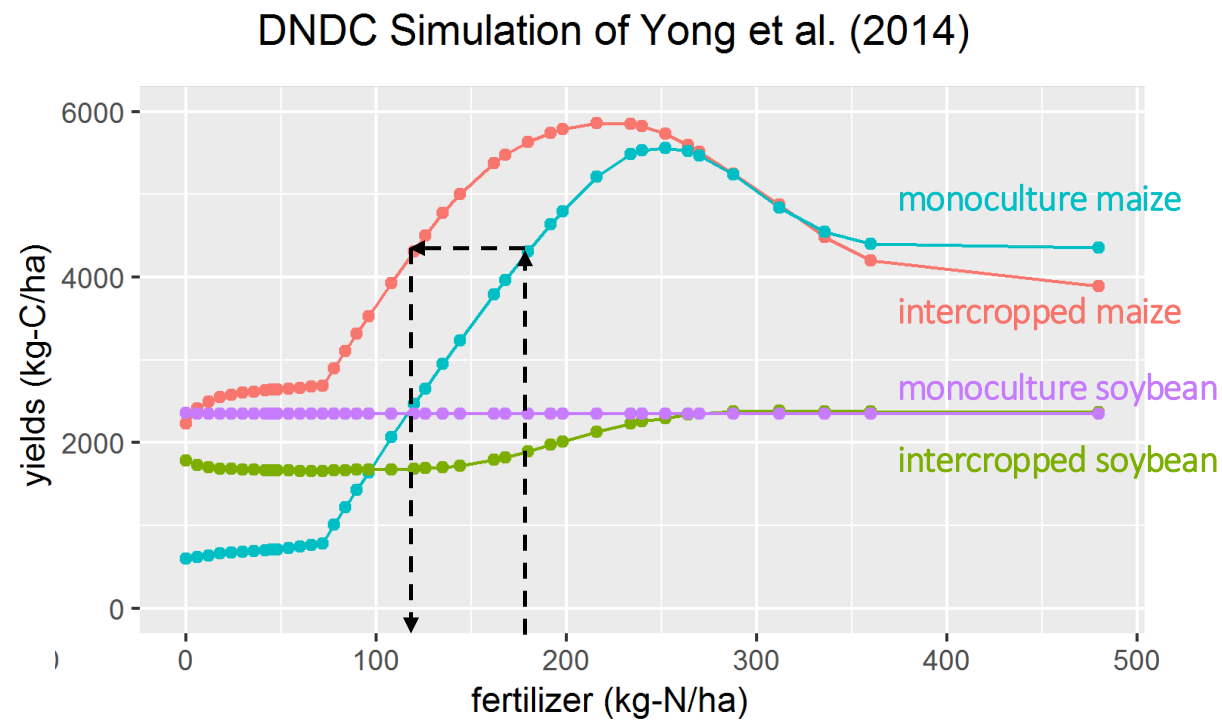

N stress under such competition stimulates soybean to fix more atmospheric N

# Modeling intercropping to explore the feasibility of a nationwide adoption

# We validate the modified DNDC and simulate a “whole-China” conversion to intercropping

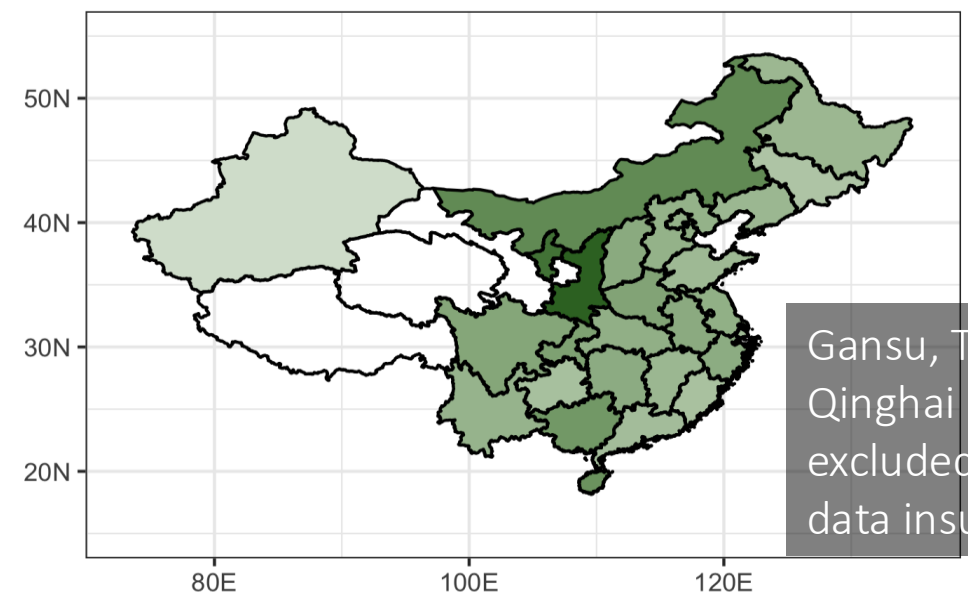

1. 33% less fertilizer to generate the same quantity of maize

2. On the same land, additional soybean can be harvested

42% less fertilizer is needed to maintain maize yield if intercropping is adopted in all maize or soybean croplands

Relative Fertilizer Usage by Province

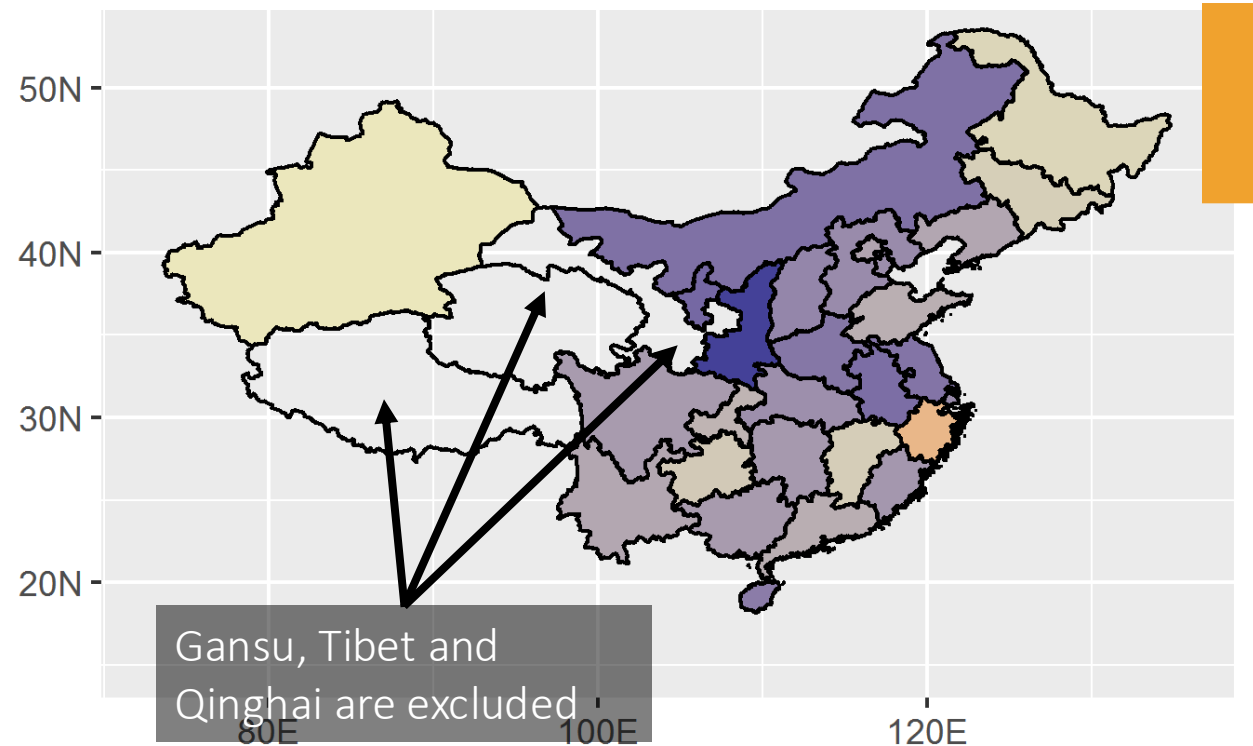

(DNDC-simulated)

# The corresponding $\text{NH}_3$ emission can be reduced by 45%

## Relative $\text{NH}_3$ Emission (Intercropping vs. Monoculture)

Fung *et al.* (2019)

Grid-by-grid  
scaling

## MASAGE $\text{NH}_3$ Emission Inventory

(Magnitude And Seasonality of  
Agricultural Emissions)

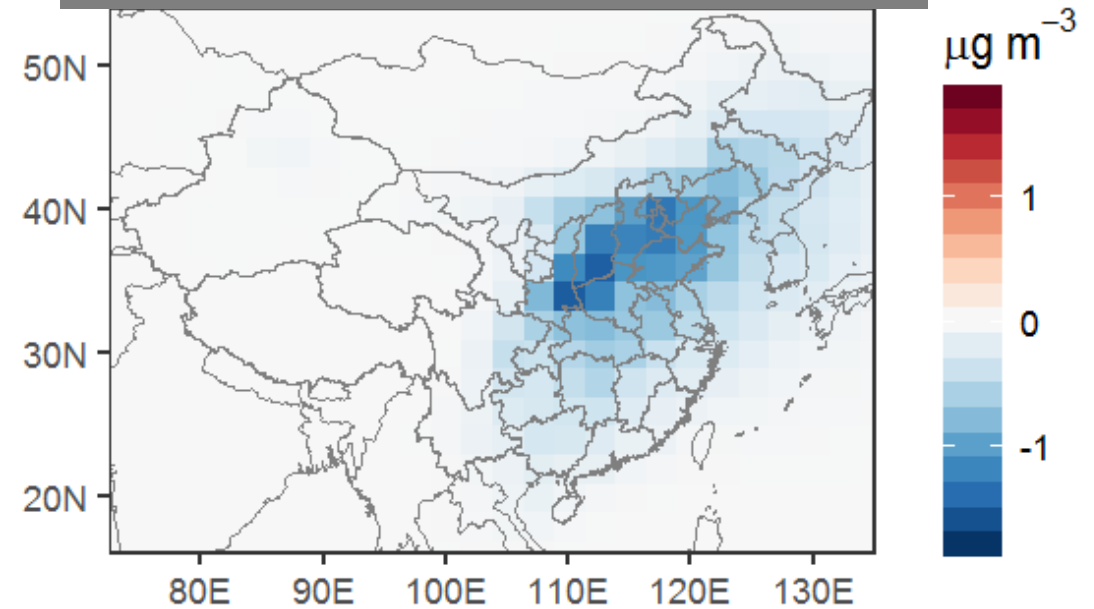

GEOS-Chem  
3-D Global Chemical Transport Model

# GEOS-Chem predicts air quality improvement if all croplands are using intercropping

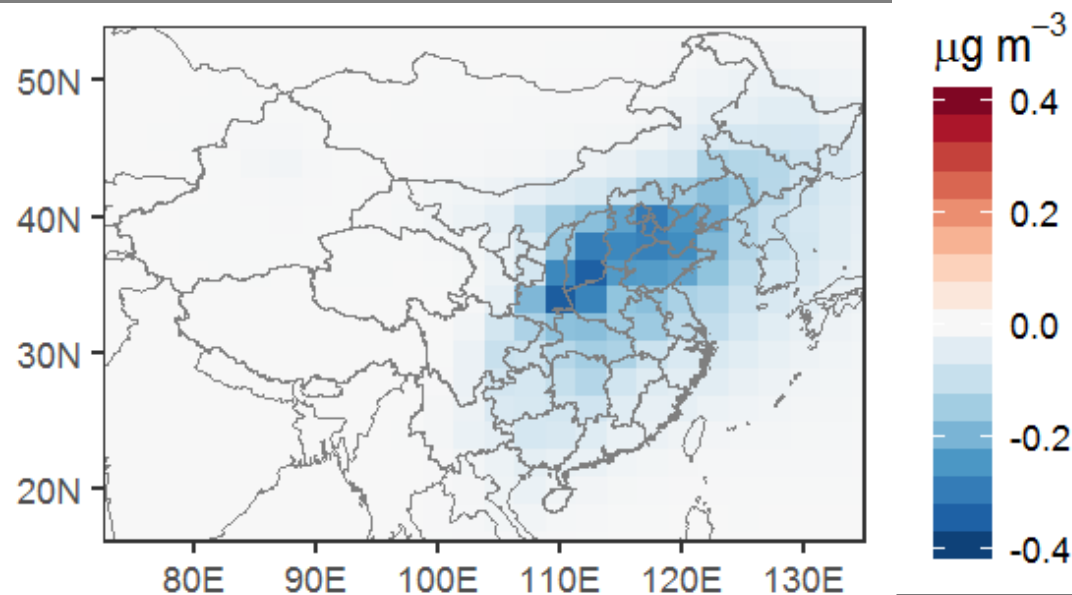

$\text{SO}_4^{2-}$   
greatest change =  $-0.081 \mu\text{g m}^{-3}$  (-1.2%)

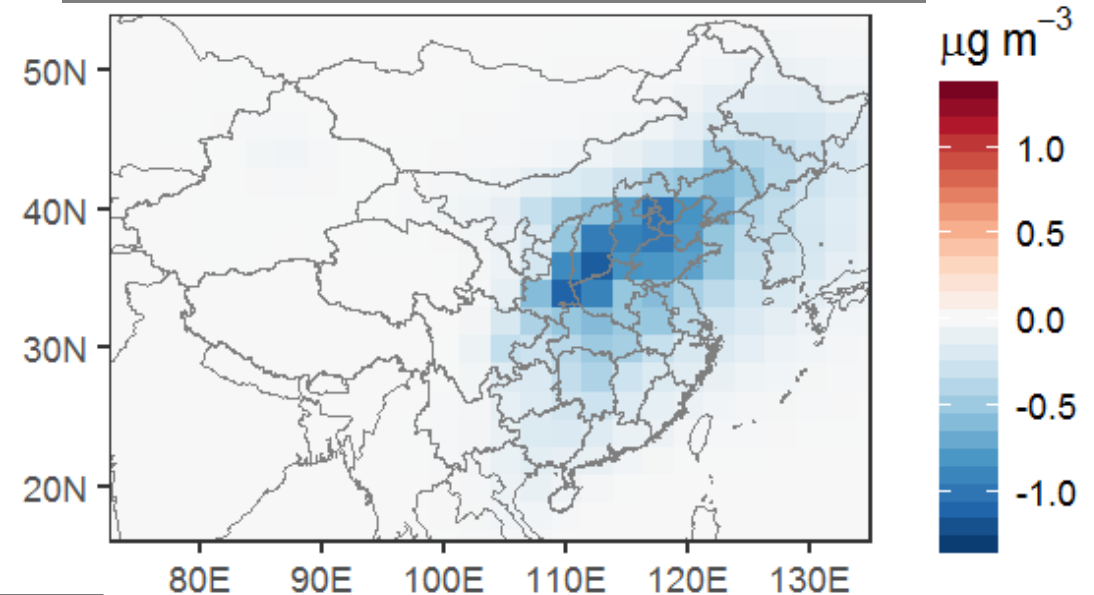

Inorganic  $\text{PM}_{2.5}$   
greatest change =  $-1.5 \mu\text{g m}^{-3}$  (-2.3%)

$\text{NH}_4^+$   
greatest change =  $-0.35 \mu\text{g m}^{-3}$  (-3.9%)

$\text{NO}_3^-$   
greatest change =  $-1.2 \mu\text{g m}^{-3}$  (-5.0%)

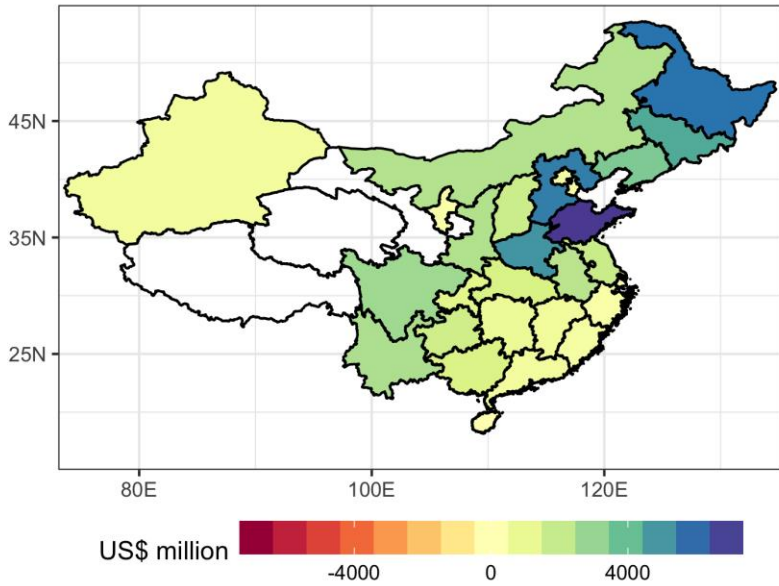

Fung *et al.* (2019)

(% to local mean without intercropping)

# Intercropping could be more economic than the current practice in China

More Grain = +US\$58b

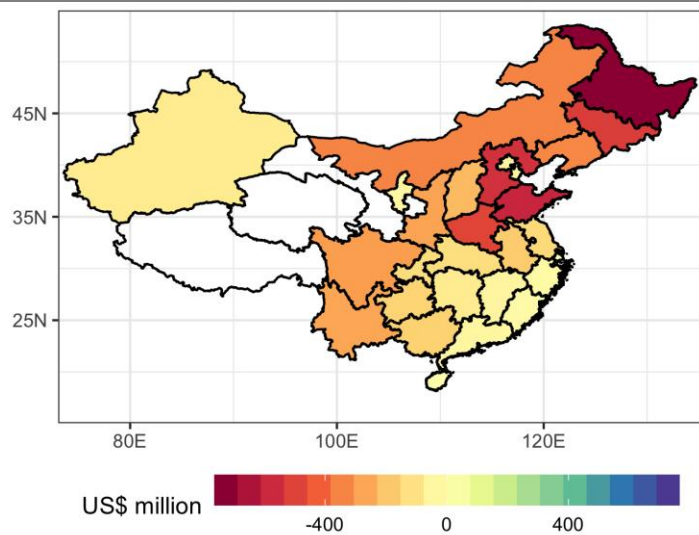

Reduced Fertilizer = +US\$0.5b

Avoided Health Costs = +US\$13b

Additional Machinery & Labor = -US\$6.0b

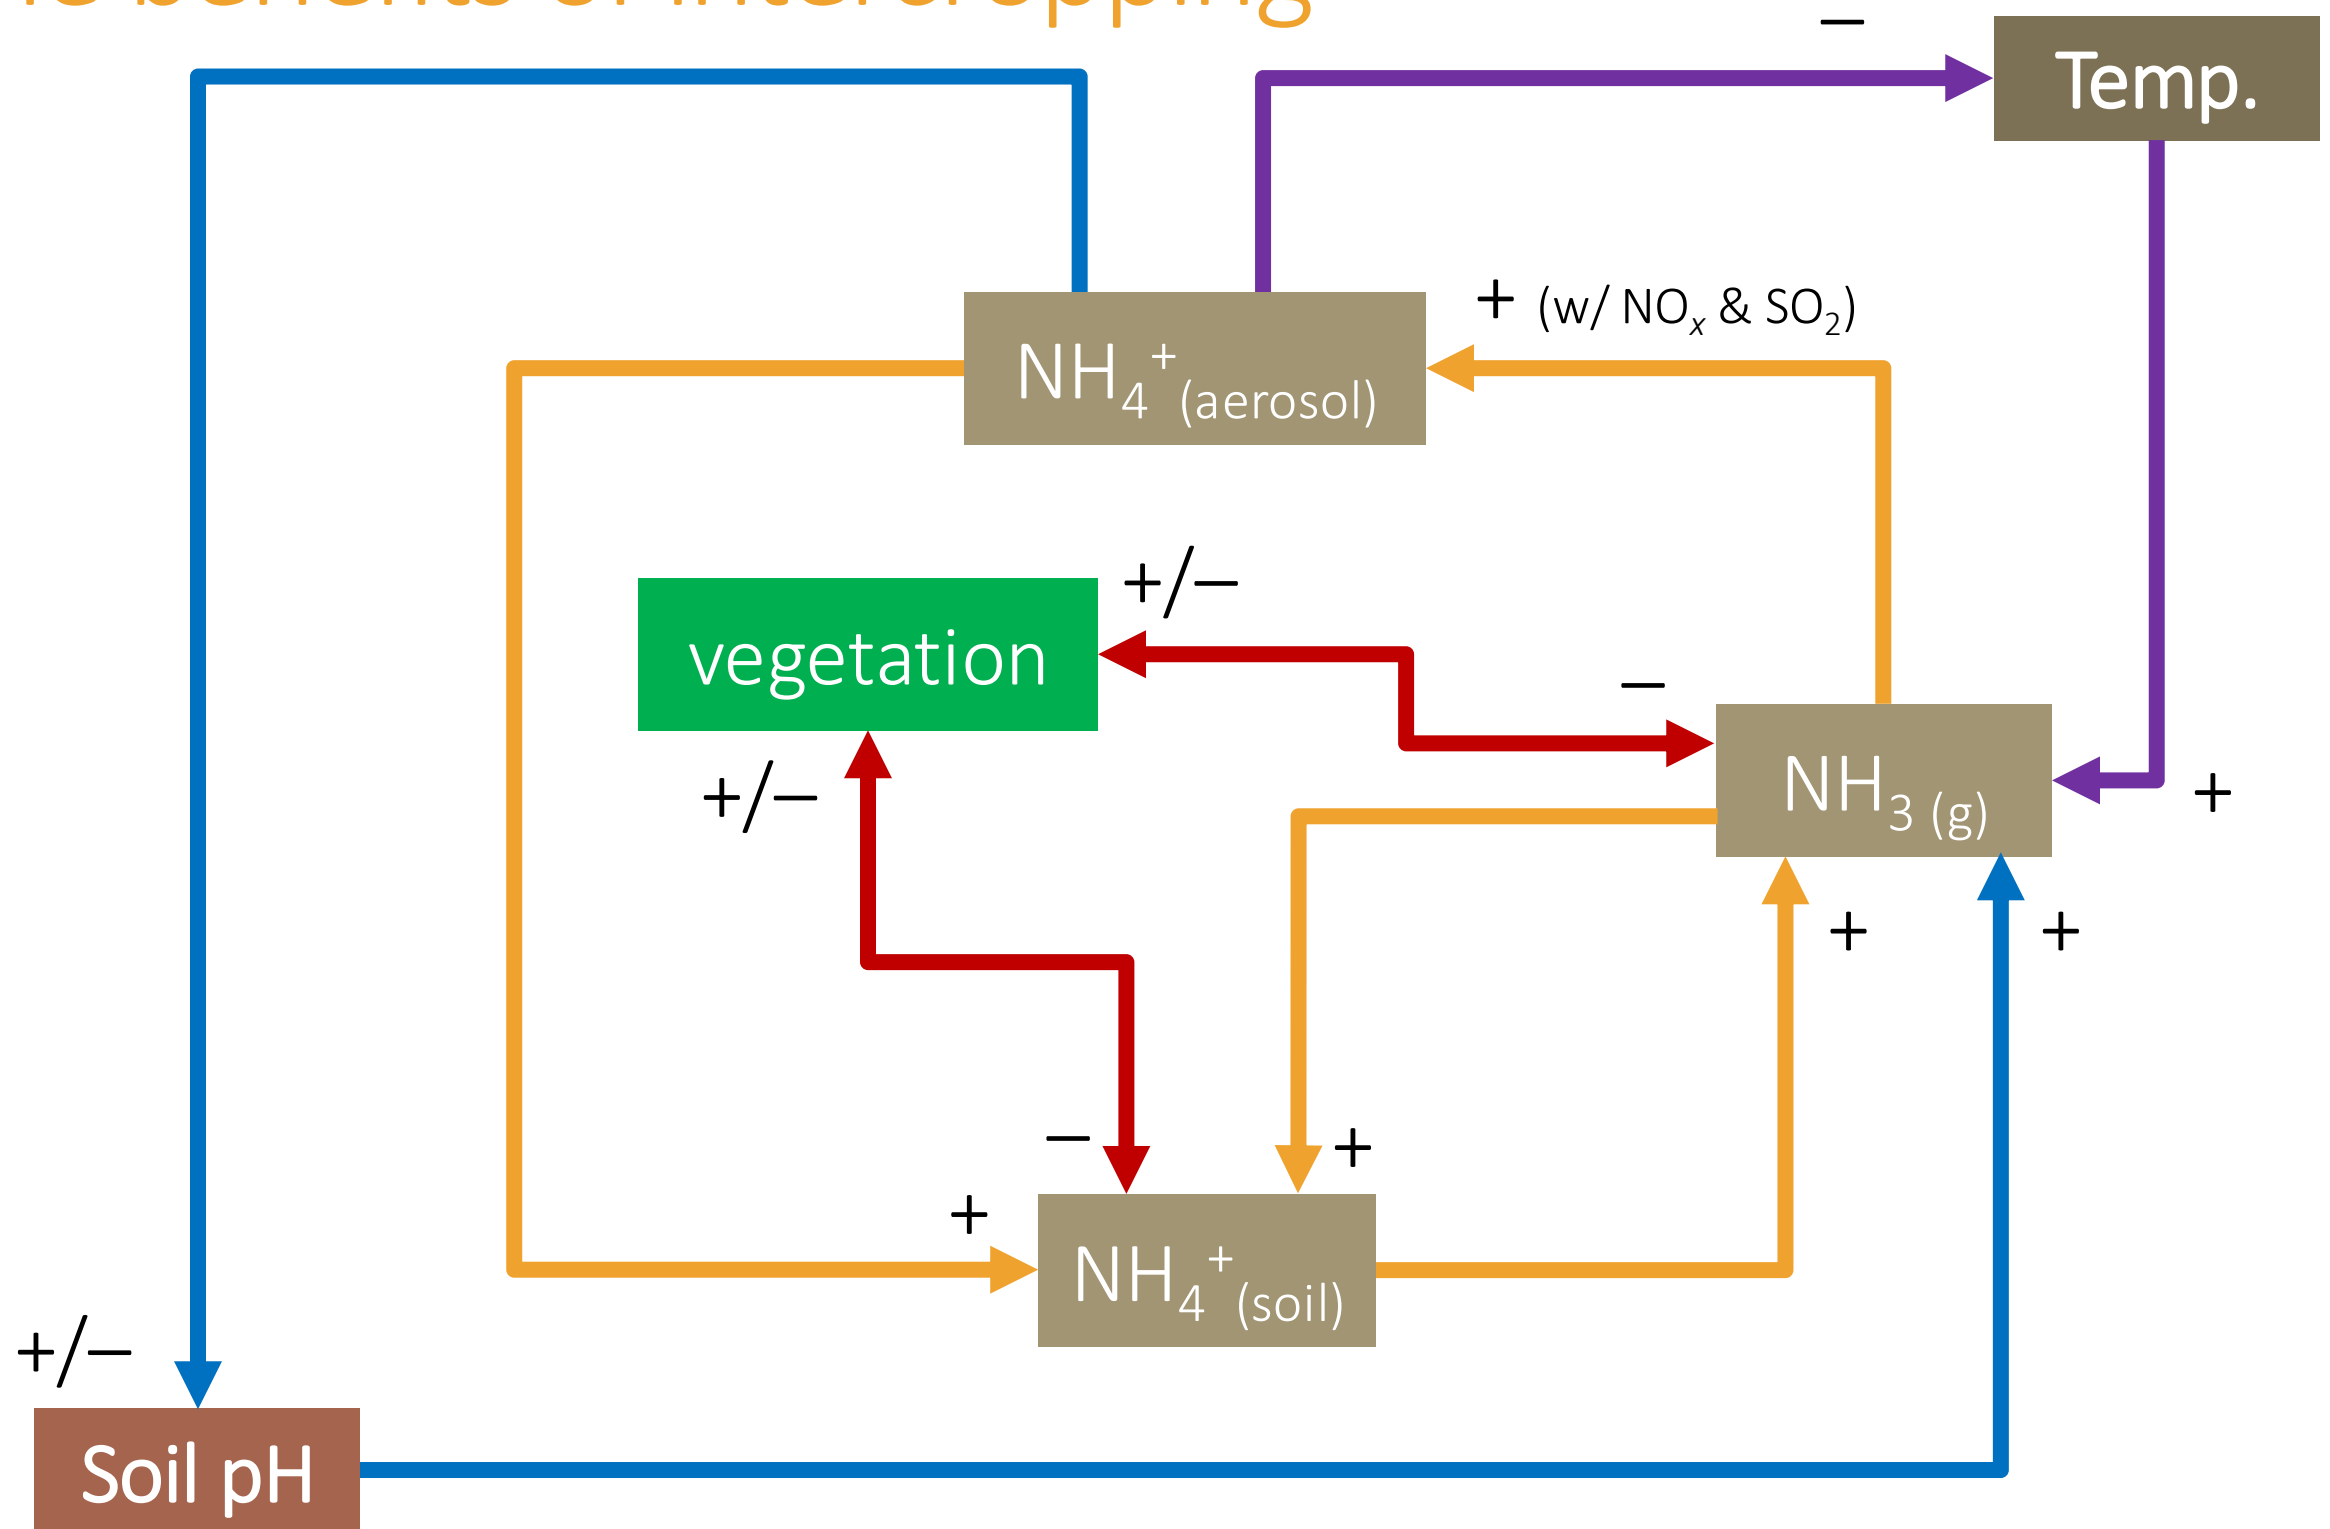

Net profit = +US\$67b  
(+93% relative to the current practice)

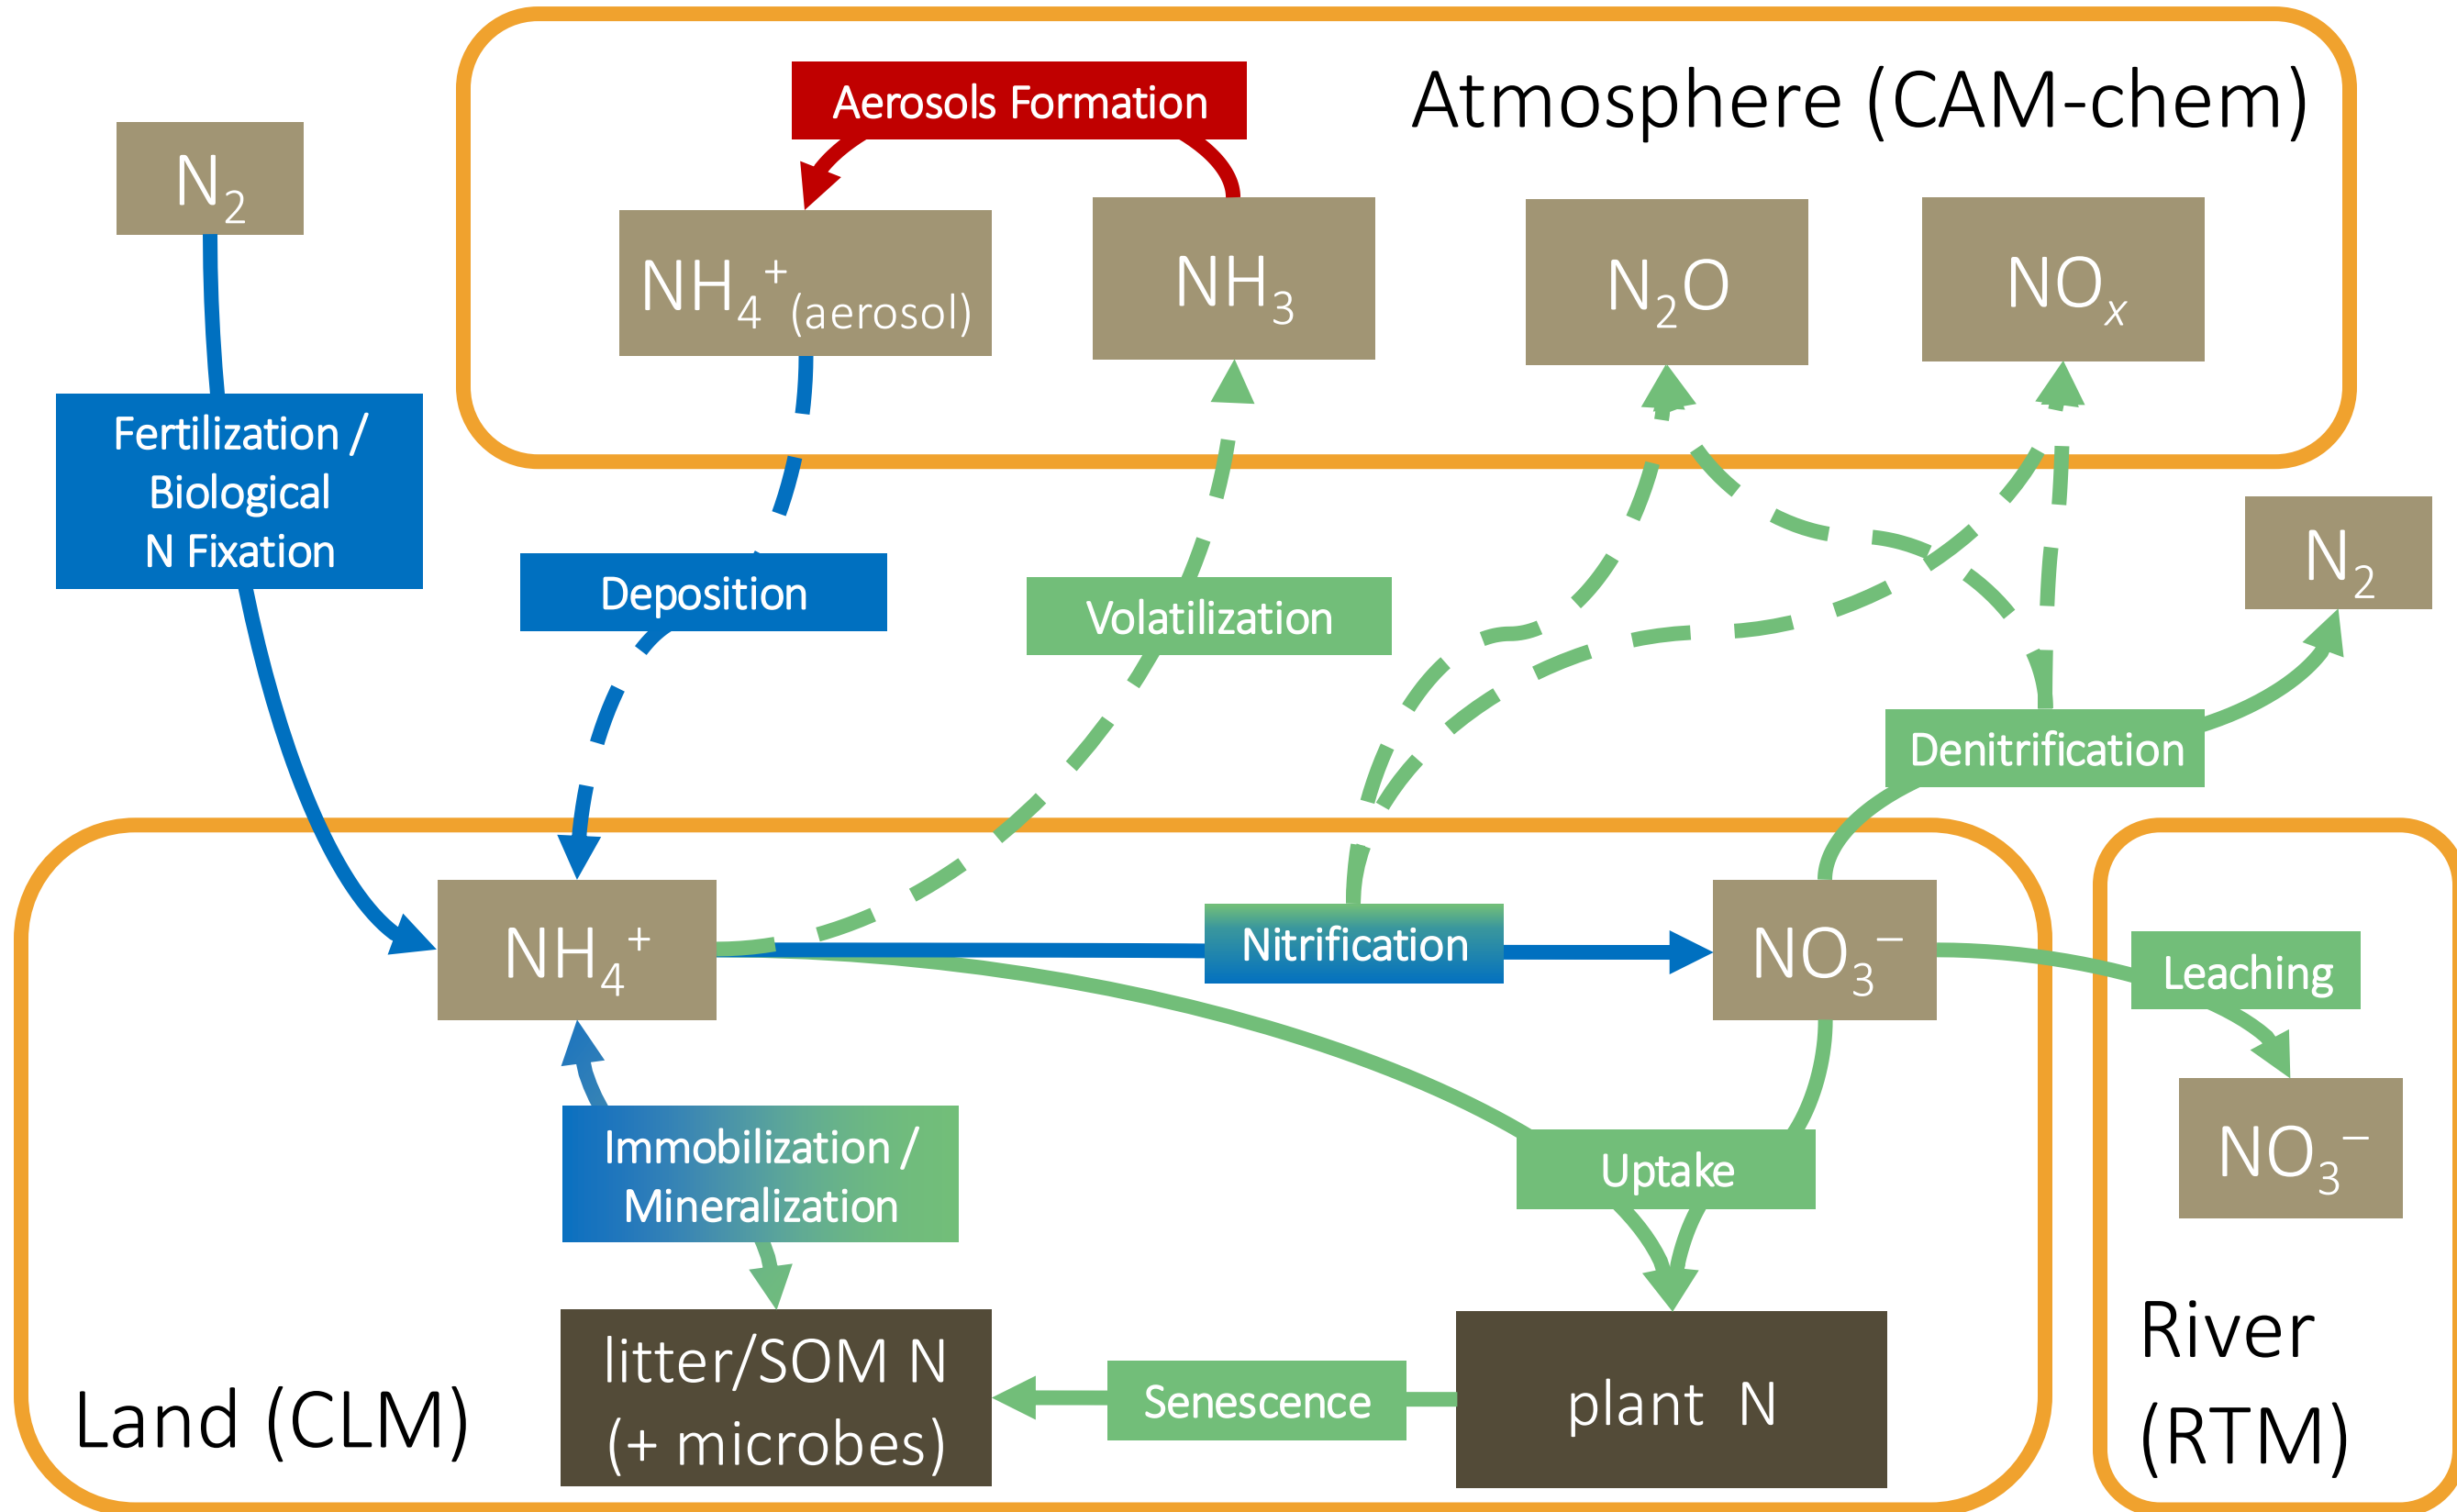

Item	US\$ Per Unit
Maize	0.25/kg
Soybean	0.41/kg
Urea	0.27/kg
Statistical Life	160k
Labor	186.50/ha
Machinery	40.00/ha

Potential feedbacks complicate the land-atmospheric  $\text{NH}_3/\text{NH}_4^+$  cycle, which may offset the benefits of intercropping

# Community Earth System Model (CESM) and its N-cycle

Fung *et al.* (in prep.)

# We implement into CLM the “multi-step” NH<sub>3</sub> emission scheme from DNDC (Li *et al.*, 2012)

$$\left(\frac{d[\text{NH}_3(\text{g})]}{dt}\right)_{\text{from soil}} \approx [\text{NH}_4^+(\text{soil})](1 - f_{\text{ads}})f_{\text{dis}}f_{\text{vol}} \left(\frac{1}{\Delta t}\right)$$

Fraction of dissociated non-adsorbed NH<sub>4</sub><sup>+</sup>:

Campbell *et al.* (2008)

rate constant of dissociation

$$f_{\text{dis}} = \frac{K_w}{[\text{H}^+]K_a}$$

soil temperature (°C)

$$K_a = (1.416 + (0.01357)T_{\text{soil}}) \times 10^{-5} \text{ (mol L}^{-1}\text{)}$$

$$K_w = 10^{0.08946 + (0.03605)T_{\text{soil}}} \times 10^{-15} \text{ (mol}^2\text{ L}^{-2}\text{)}$$

rate constant of hydrolysis

$$[\text{H}^+] = 10^{-\text{pH}} \text{ (mol L}^{-1}\text{)}$$

pH = 6.8

Fraction of NH<sub>4</sub><sup>+</sup> adsorbed to soil matrix is determined by an empirical equation:

$$f_{\text{ads}} = 0.99(7.2733f_{\text{clay}}^3 - 11.22f_{\text{clay}}^2 + 5.7198f_{\text{clay}} + 0.0263)$$

clay fraction

Fraction of volatilized NH<sub>3</sub>(aq):

soil layer depth (m)

$$f_{\text{vol}} = \left(\frac{1.5s}{1+s}\right) \left(\frac{T_{\text{soil}}}{50 + T_{\text{soil}}}\right) \left(\frac{l_{\text{max}} - l}{l_{\text{max}}}\right)$$

wind speed (m s<sup>-1</sup>)

# We further propose to calculate a prognostic canopy capture fraction

$$\left(\frac{d[\text{NH}_3(\text{g})]}{dt}\right)_{\text{thru. canopy}} = \left(\frac{d[\text{NH}_3(\text{g})]}{dt}\right)_{\text{from soil}} (1 - f_{\text{cap}})$$

Derived from DNDC (Li *et al.*, 2012) and CMAQ (Pleim *et al.*, 2013), fraction of  $\text{NH}_3$  captured by canopy is estimated as:

Account for effect of canopy height

$$f_{\text{cap}} = 14(h_{\text{top}} - h_{\text{bot}}) \times$$

Snow-free one-sided leaf area index (LAI)

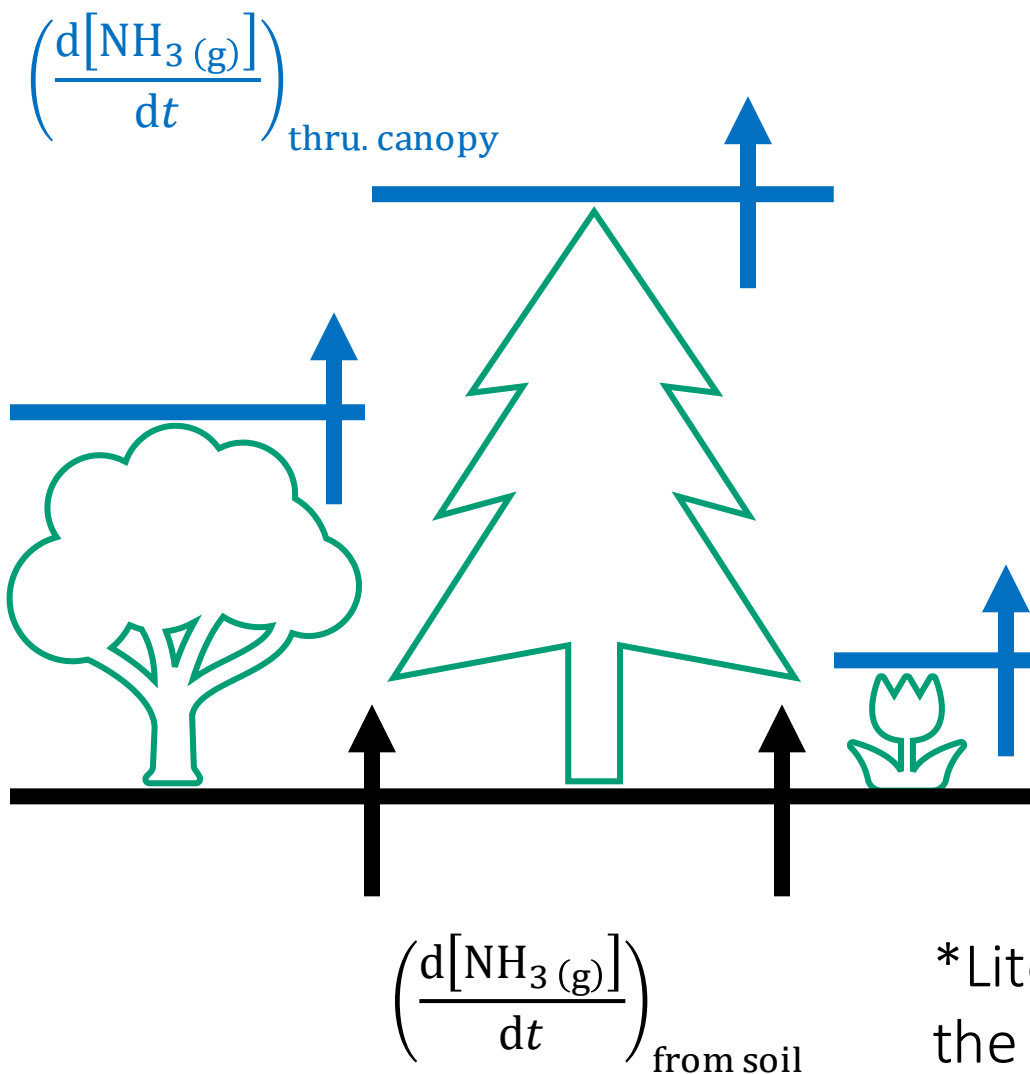

$$\text{TLAI} \times \frac{1}{v_{\text{fric}}} \times$$

frictional velocity ( $\text{m s}^{-1}$ )

$$\text{RH}_{\text{canopy}} \times v_{\text{NH}_3}$$

Relative humidity within canopy

Deposition velocity of  $\text{NH}_3$  on leaf ( $0.05 \text{ m s}^{-1}$  here)

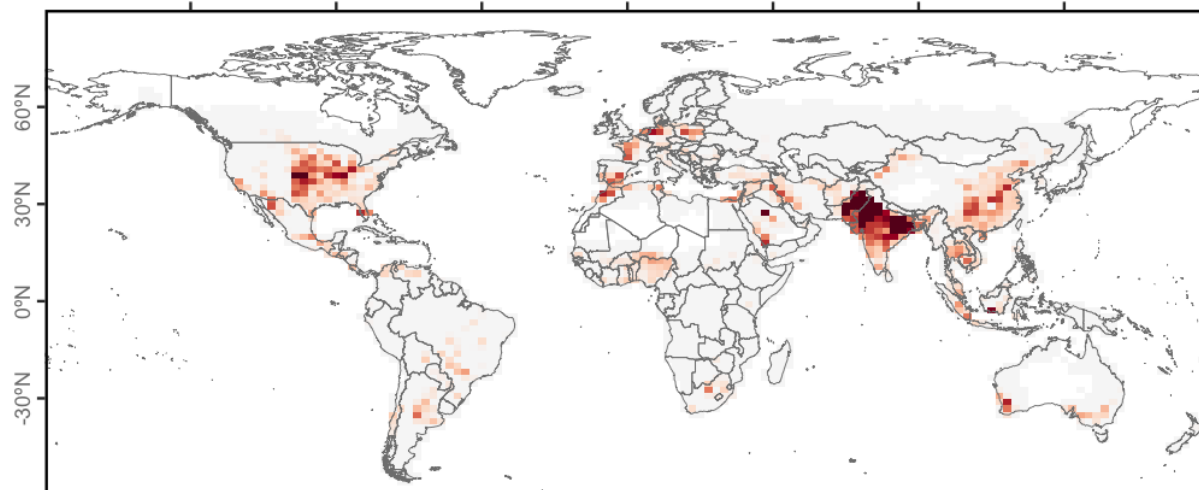

\*Literature suggests that the captured  $\text{NH}_3$  can be

- 1) metabolized
- 2) retained on leaves
- 3) returned to the soil

# Changes in cropland $\text{NH}_3$ emission driven by N deposition & aerosol-climate interactions

## Baseline

(Global Total = 15.2 Tg-N year<sup>-1</sup>)

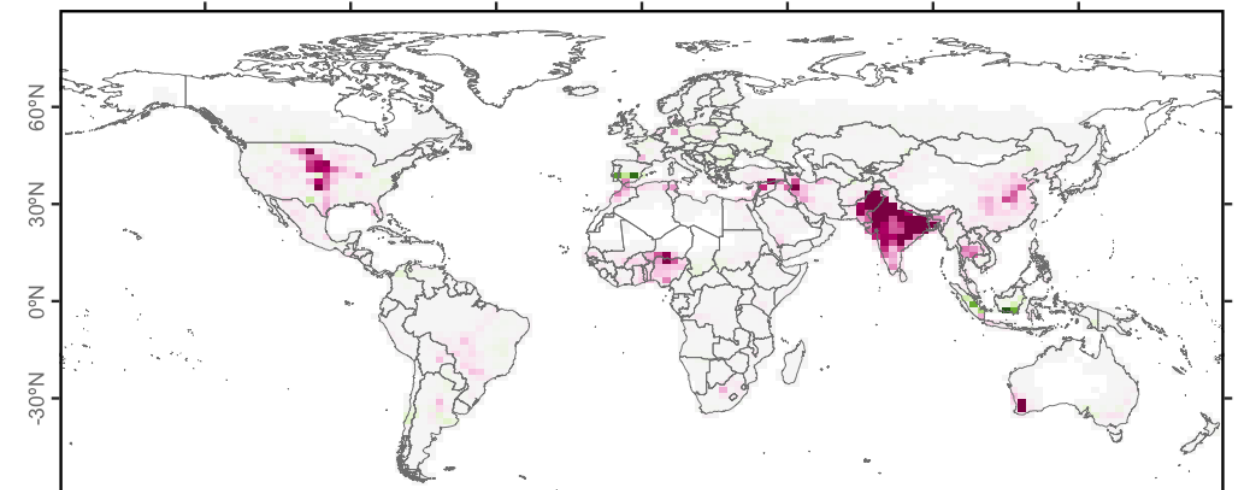

Tg grid<sup>-1</sup> year<sup>-1</sup> [1.7e-15, 0.141] (cropland only)

0.01 0.02 0.03 0.04 0.05 0.06

## $\Delta(\text{deposition})$

(Global Total = +1.7 Tg-N year<sup>-1</sup>)

- **Large-scale Intercropping in China [Fung *et al.* 2019]**
  - **Land-use Efficiency:** 200% relative yield, maize and soybean combined, on the same size of cropland and over a single planting season
  - **Nitrogen-use Efficiency:** Less fertilizer use (−42%)
  - **Environmental Sustainability:** Reduced NH<sub>3</sub> emissions (−45%) and PM<sub>2.5</sub> concentration (up to −2.3%)
  - **Profitability:** US\$67B net economic benefits including US\$13B from avoided health costs
- Fully coupled land-atmospheric NH<sub>3</sub>/NH<sub>4</sub><sup>+</sup> modeling with CESM2.0
  - **Quantifying impacts of N deposition and aerosol-climate interactions** on NH<sub>3</sub> emission and food production
- Science-based evidence to **aid policymakers in formulating sustainable agricultural plans** that safeguard food security, air quality, and environmental health
